

Guide Manual for our backend

Prerequisites

Node.js (v16 or higher) – [Download](#)

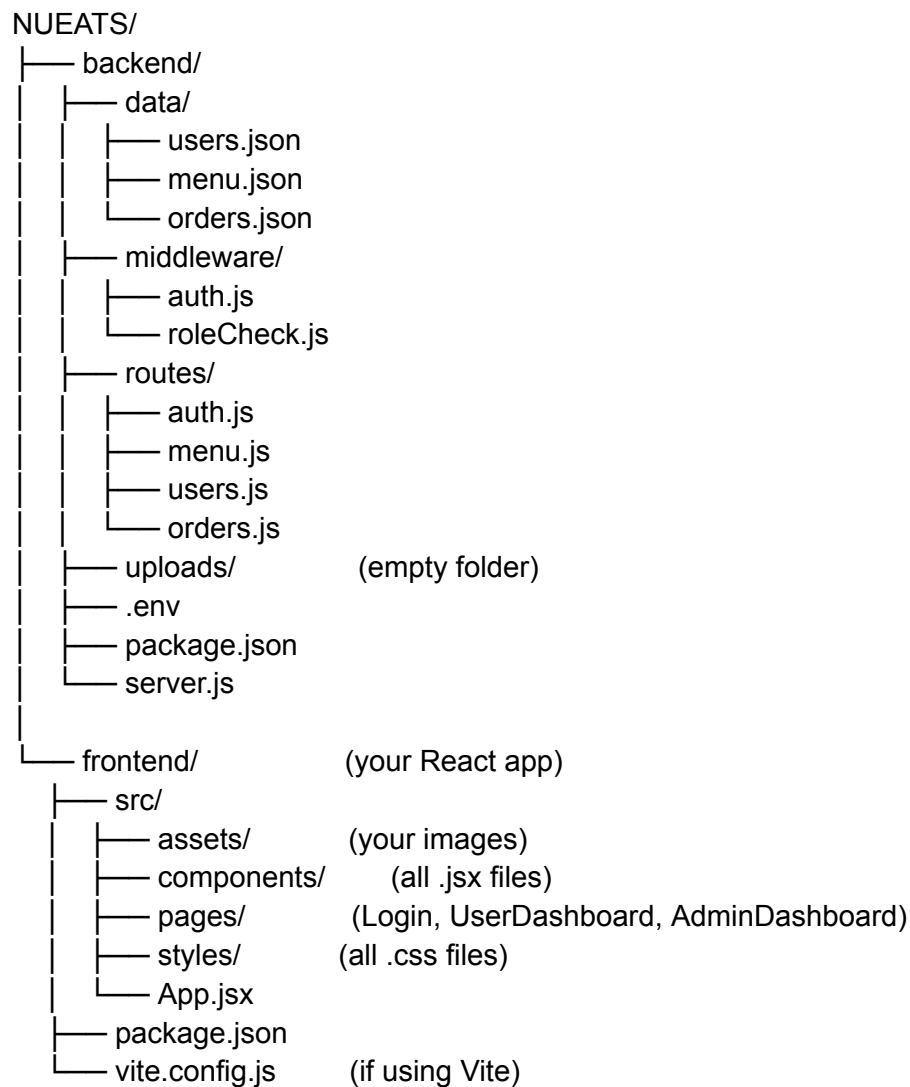

Git (optional, for cloning)

A code editor (VS Code recommended)

1. Project Structure

Make sure your project folder looks like this:

2. Backend Setup

2.1 Install dependencies

Open a terminal and navigate to the backend folder:

```
cd backend  
npm install
```

2.2 Create the .env file

Create .env with:

PORT=5000

JWT_SECRET=your_super_secret_key_change_this

2.3 Create the uploads folder

(leave it empty)

2.4 Seed the database (users and menu)

Users – backend/data/users.json

Create the file with at least one admin:

```
[  
  {  
    "id": 1,  
    "name": "Admin User",  
    "email": "admin@nueats.com",  
    "password": "$2b$10$CwTycUXWue0Thq9StjUM0uJOR9n5y3J6ahhXWZz4xXtYvKZ5y5nNi",  
    "role": "admin"  
  }  
]
```

The hash above is for the password is admin123.

Menu – backend/data/menu.json

Copy the full menu array from the previous answer (15 items) into this file.

If you don't have it, start with an empty array [] and add items later via admin panel.

Orders – backend/data/orders.json

Start empty: []

2.5 (Optional) Seed menu images

If you have images in your frontend assets/foodimages/, copy them to backend/uploads/:

Manually drag and drop, or

Run the seed-menu.js script provided earlier.

2.6 Start the backend server:

node [server.js](#)

You should see: Server running on port 5000

Keep this terminal open.

3. Frontend Setup

3.1 Install dependencies

Open a new terminal and go to your React app folder:

```
npm install
```

3.2 Configure the API URL

In every file that calls fetch, make sure the URL points to `http://localhost:5000/api/...`

For example, in `src/pages/Login.jsx`:

```
fetch('http://localhost:5000/api/auth/login', ...)
```

Alternatively, use a proxy (recommended for Vite). Create [vite.config.js](#):

```
import { defineConfig } from 'vite'
```

```
import react from '@vitejs/plugin-react'
```

```
export default defineConfig({
  plugins: [react()],
  server: {
    proxy: {
      '/api': {
        target: 'http://localhost:5000',
        changeOrigin: true,
      }
    }
  }
})
```

Then use relative paths: `fetch('/api/auth/login', ...)`

3.3 Start the frontend development server:

```
npm run dev
```

You will see something like:

```
VITE v5.0.0 ready in 300 ms
```

```
➔ Local: http://localhost:5173/
```

3.4 Open the website

Go to `http://localhost:5173` in your browser.
You will be redirected to `/login`.

Role	Email	Password
Admin	<code>admin@nueats.com</code>	<code>admin123</code>
User	(create via admin)	

Additional addition for password hashing

4.1 To add a hashing

Use the code below: (insert manually)

```
cd backend
node hash.js
```

Notes: (problems and suggestions):

Problem 1:

There's a problem where the user can login but the admin can't log in through the server since it conflicts with their credentials

Solution: Find a way to remove the conflict

Problem 2:

There's a problem where the user is done ordering, it doesn't show a receipt or a history of the transaction

Solution: Make a receipt tab where the user can verify their orders or just show the history of it

Problem 3:

There's a problem around the admin page wherein the UI sometimes gets stuck, but overall, the admin panel is quite great since I can add or remove the food items, giving it a complete touch to our system. The problem occurs when the price range sometimes doesn't get updated

Solution: Find a way to eliminate the problem, then find a way to sync the proper price range to the system (technically, PHP 999) is too much for a Coke or a burger, but you get my point

Problem 4:

The Profile UI is too bland. What I meant by too bland is that it doesn't even have any profile details of the user, like for example, there's no profile picture or credentials that are needed to verify the user

Solution: Make a simple retrofit of the ui regarding the profile tab

Problem 5:

The Background is too bland and dull. We can make it more lively, but I'll leave it up to you guys

Solution: Find a way to make it lively overall; the UI is pretty decent already

Problem 6:

Another problem on our website is the search bar, I can't seem to integrate it into our backend system

Solution: make it work.. The search engine should work so the customer/user knows what to buy

Suggestions:

1. Add 5 more items to the Menu
2. Add a Wallet or GCash option (QR) (optional: since our time is very limited)

Additional Note: That's all I can think about right now. Feel free to add more suggestions in the future.

All the files that I updated are uploaded to my GitHub repo:

<https://github.com/debug-phantom/NU-EATS-CLONE-REPO-ONLY-WITH-BACKEND>

Working na yung:

1. Nakakapag order na then naaccept na ng system yung order
2. Sa admin panel gumagana nadin sya napapalitan na din ng presyo yung mga food item
3. Login/Logout Feature
4. Navieview na din yung profile
